Abstract

RASSF1A promoter methylation has been correlated with tumor dedifferentiation and aggressive oncogenic behavior. Nevertheless, the underlying mechanism of RASSF1A-dependent tumor dedifferentiation remains elusive. Here, we show that RASSF1A directly uncouples the NOTCH-HES1 axis, a key suppressor of differentiation. Interestingly, the crosstalk of RASSF1A with HES1 occurs independently from the signaling route connecting RASSF1A with the Hippo pathway. At the molecular level, we demonstrate that RASSF1A acts as a scaffold essential for the SUMO-targeted E3 ligase SNURF/RNF4 to target HES1 for degradation. The reciprocal relationship between RASSF1A and HES1 is evident across a wide range of human tumors, highlighting the clinical significance of the identified pathway. We show that HES1 upregulation in a RASSF1A-depleted environment renders cells non-responsive to the downstream effects of γ -secretase inhibitors (GSIs) which restrict signaling at the level of the NOTCH receptor. Taken together, we report a mechanism through which RASSF1A exerts autonomous regulation of the critical Notch effector HES1, thus classifying RASSF1A expression as an integral determinant of the clinical effectiveness of Notch inhibitors.

Introduction

RASSF1A epigenetic inactivation correlates with poor clinicopathological characteristics in the vast majority of human solid malignancies (Grawenda & O'Neill, 2015). RASSF1A is a key mediator of Hippo pathway activity and facilitates transcription factor selection for the Hippo effector YAP (Hamilton *et al*, 2009; van der Weyden *et al*, 2012; Pefani *et al*, 2016). In addition to its tumor-suppressive role, RASSF1A undergoes stringent epigenetic regulation throughout early embryonic development to allow smooth transition from pluripotency to differentiation (Papaspyropoulos *et al*, 2018).

Tumorigenesis and somatic cell reprogramming are governed by similar mechanisms, as tumor progression is the outcome of dedifferentiation processes (Friedmann-Morvinski & Verma, 2014). Tumor dedifferentiation has been linked with upregulation of stem cell (SC) markers, such as OCT4, NANOG, and SOX2 and their target genes, which are normally enriched in embryonic stem cells (ESCs) (Friedmann-Morvinski & Verma, 2014; Hepburn *et al*, 2019).

Current findings support that Notch signaling holds a crucial role in inducing tumor dedifferentiation. Activation of the NOTCH1-HES1 axis in solid tumors results in increased epithelial-to-mesenchymal transition (EMT) accompanied by upregulation of stemness genes (Reedijk *et al*, 2008; Fender *et al*, 2015; Jin *et al*, 2017; Fendler *et al*, 2020). The NOTCH-HES1 axis can be effectively disrupted by γ -secretase inhibitors (GSIs) preventing the proteolytic cleavage of the NOTCH receptor and subsequent translocation of its intracellular domain (NICD) to the nucleus, thereby abrogating both Notch signaling and SC marker expression (Chu *et al*, 2013).

In this study, we present a novel mechanism through which RASSF1A prevents tumor dedifferentiation by triggering HES1

degradation in a Hippo-independent manner. The significance of the identified pathway is depicted in a wide spectrum of human malignancies, whereas employing NOTCH inhibitors defines the precise clinical setting for potential therapeutic intervention.

Results and Discussion

RASSF1A levels inversely correlate with HES1 expression across human tumor types

We previously showed that NOTCH signaling negatively correlates with RASSF1A in human tumors such as breast and lung (Pefani *et al*, 2016). The Notch target HES1 is a basic helix-loop-helix (bHLH) transcriptional regulator (Artavanis-Tsakonas *et al*, 1999) which promotes CSC self-renewal (Gao *et al*, 2014). To investigate a potential RASSF1A-HES1 regulation, we analyzed RNA sequencing (RNA-seq) data from The Cancer Genome Atlas (TCGA) and the Genotype-Tissue Expression (GTEx) portal deriving from 32 different human tumor types arising in different organs ($n = 9,527$ samples). Interestingly, we found that RASSF1A and HES1 are reciprocally expressed across whole patient cohorts for tumors with both high (Fig 1A and Dataset EV1) and low (Fig 1B and Dataset EV1) levels of RASSF1A. Along the same lines, a correlative analysis implementing again RNA-seq data from the TCGA and GTEx cancer databases demonstrated a statistically significant ($P < 0.01$) negative correlation of RASSF1A with HES1 levels across all tumor types (Fig 1C and Dataset EV1). In line with our clinical data (Fig 1D), upon silencing of RASSF1A, HES1 levels were significantly increased in both human osteosarcoma (U2OS) and cervical cancer (HeLa) cells (Fig 1E and F), implying that RASSF1A may functionally regulate HES1. RASSF1A and HES1 Transcripts Per Million (TPMs) in normal tissues (Fig 1D) were only included to provide a rough estimation of how deregulated the expression of each marker may be in cancer compared to normal tissue. A limitation to this estimation may derive from the small sample size of two normal tissue types (the respective of cervical cancer-CESC and sarcoma-SARC) which relates to their poor representation by the TCGA database.

To identify potential RASSF1A-dependent regulators of HES1, we analyzed TCGA data from clinical samples expressing high and low RASSF1A levels (Fig EV1A and Dataset EV1). One of the top hits significantly correlating with RASSF1A levels was the transcription factor GATA1 ($P < 0.00001$; Fig EV1A), a *HES1* transcriptional repressor (Ross *et al*, 2012). Indeed, GATA1 depletion led to HES1 upregulation in our system (Fig EV1B). Interestingly, GATA1 levels were found decreased upon silencing of the Hippo pathway component Mst1/2 in *Xenopus* embryos (Nejigane *et al*, 2013), likely indicating dependency on RASSF1A which functions as an MST2 activator (Matallanas *et al*, 2007). In support of this, RASSF1A depletion and overexpression in U2OS cells resulted in GATA1 reduction and increase, respectively (Fig EV1C and D), indicating that GATA1 may be responsible for HES1 regulation by RASSF1A at the transcriptional level.

The observation that HES1 mRNA levels follow the HES1 protein stabilization pattern after RASSF1A modulation (Fig 1E and F) is in keeping with the presence of deeply characterized feedback loops in the case of HES1, where the amount of HES1 protein or its targets in the cell determine *HES1* gene transcription rate (Kobayashi *et al*,

2009; Roesse-Koerner *et al*, 2017; Duan *et al*, 2019). Similarly to HES1, which is expressed in cells and tissues in an oscillatory fashion (Kobayashi *et al*, 2009; Roesse-Koerner *et al*, 2017), RASSF1A levels have also been described to oscillate through the cell cycle via degradation by SCF E3 ligase (Song *et al*, 2008) suggesting that these regulatory processes may be linked.

Given that HES1 can be both nuclear and cytoplasmic (Sturrock *et al*, 2014), we next asked whether RASSF1A-HES1 regulation may differentially affect HES1 protein levels in the nuclear and cytoplasmic fraction. We employed a U2OS Tet-On cell line inducibly expressing FLAG-RASSF1A (U2OS^{Tet ON} - FLAG-RASSF1A) upon doxycycline treatment and assessed HES1 protein levels following subcellular fractionation. Interestingly, consistent with a recently described RASSF1A function in nucleocytoplasmic protein transfer and nuclear RASSF1A localization (Chatzifrangkeskou *et al*, 2019), RASSF1A expression reduced only the nuclear HES1 pool while cytoplasmic HES1 levels remained unaffected (Figs 1G and EV2A).

RASSF1A stabilizes the E3 ligase RNF4 to inactivate HES1 through formation of a RASSF1A-RNF4-HES1 complex

Apart from RASSF1A regulating HES1 expression, a proteomic screen for RASSF1A binding partners surprisingly identified HES1 itself as a potential interactor (Dataset EV2), suggesting that RASSF1A-HES1 regulation may expand to the post-translational level thereby affecting HES1 stability. In our proteomic screen (Dataset EV2), we also identified the E3 ubiquitin ligase SNURF/RNF4, whose *Drosophila* ortholog Degringolade (Dgrn) was shown to target HES proteins for SUMO-independent ubiquitination *in vitro* and *in vivo* (Abed *et al*, 2011; Barry *et al*, 2011). Additionally, a Sleeping Beauty genetic screen carried out in *Rassf1a*^{-/-} mice identified *RNF4* among the potentially most frequently inactivated genes synergizing with RASSF1A loss in tumorigenesis (van der Weyden *et al*, 2012).

HES1 has been found to be degraded by additional E3 ligases in different contexts. For example, the E3 ubiquitin ligase SCF^{FBXL14} complex targets HES1 for proteolysis, thereby enabling neuronal differentiation (Chen *et al*, 2017). As previously published reports (Abed *et al*, 2011; Barry *et al*, 2011; van der Weyden *et al*, 2012) and our proteomic data strongly pointed to RNF4 as a potential player affecting RASSF1A-HES1 regulation in cancer cells, we were urged to explore a possible connection.

Interestingly, RASSF1A expression in U2OS cells led to significant stabilization of RNF4 protein levels (Fig 2A). HES1 and RNF4 were both identified as co-immunoprecipitating in U2OS cells supporting the regulatory connection, while the HES1/RNF4 ratio was decreased in the presence of FLAG-RASSF1A, suggesting the interaction is supported by RASSF1A (Fig 2B). Moreover, HES1 was found associated with both RNF4 and RASSF1A, confirming the presence of a RASSF1A-RNF4-HES1 complex, concomitant with a reduction of HES1 protein levels (Fig 2B). To confirm that RNF4 was directly responsible for the decrease of HES1 upon RASSF1A activation, we overexpressed RASSF1A in the presence or absence of an RNF4-targeting siRNA and assessed HES1 ubiquitination levels in HES1 immunoprecipitates (Fig 2C). In accordance with data above, RASSF1A overexpression stabilized RNF4 with a concomitant reduction in HES1 levels due to increased HES1 ubiquitination (Fig 2C). However, depletion of RNF4 rescued HES1 despite RASSF1A

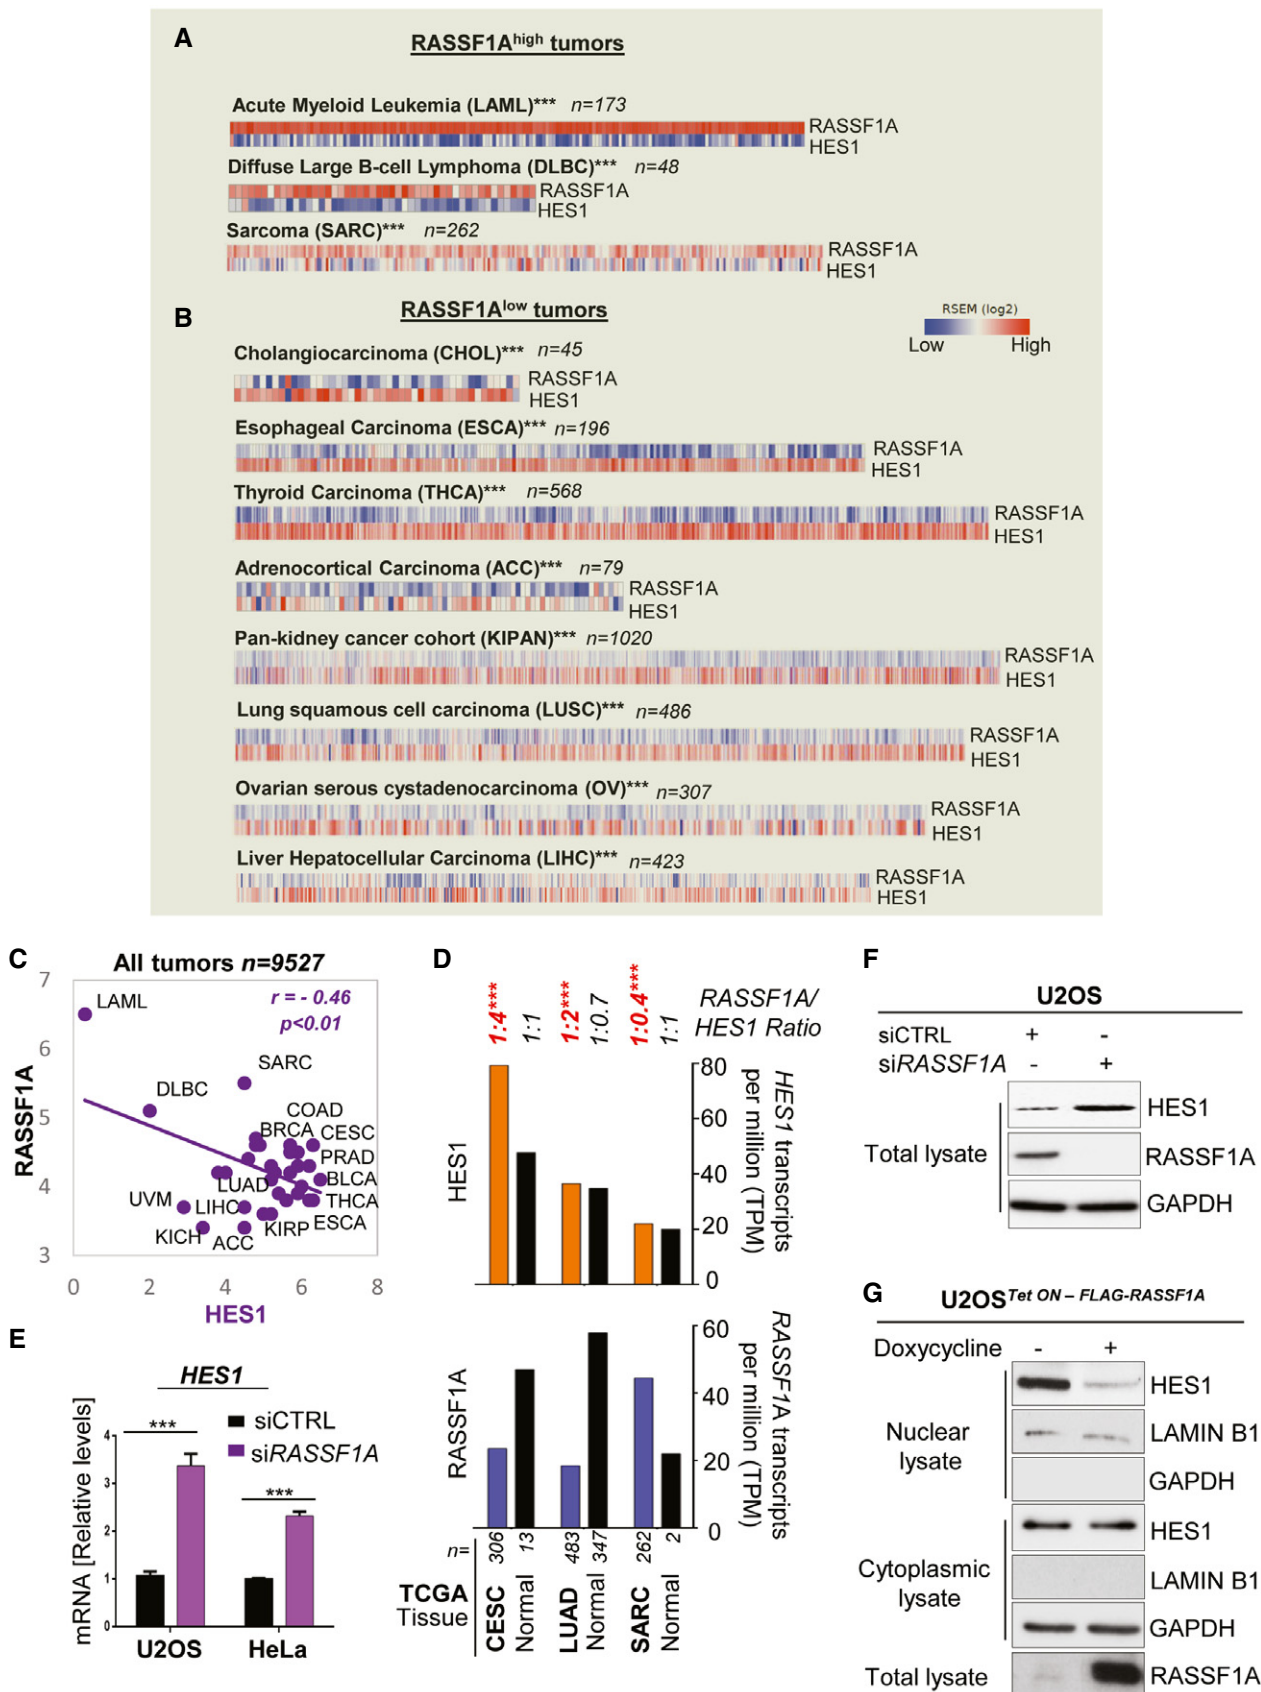

Figure 1.

Figure 1. The RASSF1A expression pattern is reciprocal to HES1 across human tumor types.

- A Correlation heatmaps depicting an opposite RASSF1A-HES1 expression pattern across the tumors with highest expression of RASSF1A. RNA seq data were retrieved from the TCGA database. Of the 32 tumor types of the TCGA database included in the analysis, tumor types with an average of > 4.2 (median) RASSF1A Transcripts per million (TPM) were classified as RASSF1A^{high}, whereas tumor types with an average of < 4.2 RASSF1A TPM were classified as RASSF1A^{low}. See also Dataset EV1.
- B Same as A, for the TCGA tumors with the lowest expression of RASSF1A. See also Dataset EV1.
- C Correlation analysis between RASSF1A and HES1 levels across 32 human tumor types (*n* indicates total number of tumor samples). RNA seq data were retrieved from the TCGA and GTEx databases and analyzed using the GEPIA/GEPIA2 online tools (Tang *et al*, 2017, 2019). See also Dataset EV1.
- D RASSF1A (bottom) and HES1 (top) transcripts per million (TPM) in the indicated types of human tumors and respective normal tissue. Data were extracted from the TCGA and GTEx databases using the GEPIA/GEPIA2 online tool for normal and cancer gene expression profiling and interactive analyses. The number of patients is indicated in each tumor type. See also Dataset EV1.
- E qPCR for HES1 mRNA levels in siCTRL (non-targeting) and siRASSF1A-transfected U2OS and HeLa cells.
- F U2OS cells were transfected with either siCTRL or siRASSF1A and lysates were immunoblotted for HES1 levels.
- G U2OS cells Tet-On inducibly expressing FLAG-RASSF1A were treated with doxycycline at a concentration of 0.5 µg/ml for 24 h. The cells were fractionated in order to acquire the nuclear and cytoplasmic extracts, which were subsequently Western blotted and probed with the indicated antibodies.

overexpression (Fig 2C), confirming that RNF4 is required for RASSF1A-mediated HES1 regulation. In keeping with previous results suggesting that RASSF1A-HES1 regulation is nuclear, we found that HES1 was ubiquitinated predominantly in the nuclear fraction of U2OS cells, upon RASSF1A induction (Fig EV2B and C). Our observations in cells were further validated in an *in vitro* ubiquitination assay showing increased RNF4-mediated HES1 ubiquitination in the presence of RASSF1A (Fig 2D). Taken together, our data uncover a novel mechanism through which RASSF1A regulates the NOTCH effector HES1, via the E3 ligase RNF4 (Fig 2E).

RASSF1A regulates HES1 activity in a Hippo pathway-independent manner

RASSF1A epigenetic inactivation has been found to directly induce the expression of the core pluripotency gene *Pou5f1/Oct4* in mouse ESCs and pre-implantation embryogenesis through the Hippo pathway effector YAP (Papaspyropoulos *et al*, 2018). Although mouse models have proven vital tools in recapitulating human disorders, substantial differences occur between the two species, rendering confirmation in human settings essential (Perlman, 2016). Therefore, we sought to investigate whether RASSF1A may exert a similar regulation of pluripotency genes in human cancer cells. To this end, we silenced RASSF1A in HeLa and U2OS cells and found that the core pluripotency markers were upregulated at the protein (Fig EV3A, B and D) and mRNA (Fig EV3C) level. To verify that those effects were RASSF1A-mediated, we induced RASSF1A expression in U2OS^{Tet ON - FLAG-RASSF1A} cells and confirmed that RASSF1A induction was indeed sufficient to restrict endogenous expression of all core pluripotency markers (Fig EV3E).

In accordance with our previous findings, ectopic expression of RASSF1A in a non-small cell lung carcinoma cell line (H1299) subjected to a two-dimensional (2D) differentiation assay, completely abrogated SC marker expression and forced cell colonies to lose their round shape, indicating acquisition of a differentiated phenotype (Fig EV4A and B). The RASSF1A-mediated differentiation

phenotype was additionally accompanied by loss of HES1 expression, while RNF4 was markedly stabilized (Fig EV4C).

Our previous work in ESCs and pre-implantation embryonic development revealed that forced RASSF1A silencing aberrantly activated the core pluripotency network, but to no obvious developmental defects in the mouse embryo. Consistently, *Rassf1a*^{-/-} mice appear to develop normally and be fertile; however, they are prone to spontaneous tumor formation (Tommasi *et al*, 2005; van der Weyden *et al*, 2005). Our current data showing that RASSF1A drives tumor differentiation through downregulation of core pluripotency genes provide a potential explanation for the pronounced tumor predisposition observed in *Rassf1a*^{-/-} mice.

In order to determine whether RASSF1A-HES1 regulation may act independently from the Hippo pathway, we evaluated HES1 level changes in response to RASSF1A depletion, upon additional silencing of the Hippo effectors YAP/TAZ. While RASSF1A depletion expectedly increased HES1 levels and destabilized RNF4, additional single knockdowns of YAP or TAZ or dual YAP/TAZ depletion were not accompanied by differences in HES1 or RNF4 levels, confirmed in two independent cell lines (Fig EV5A). Conversely, HES1 reduction in response to RASSF1A was not perturbed by additional induction of active YAP or its phosphorylation-defective mutant YAP S127A (Fig EV5B). Thus, our data strongly indicate that RASSF1A may control HES1 activity away from its role as a Hippo pathway scaffold.

RASSF1A overrides Notch signaling to autonomously regulate the NOTCH downstream effector HES1 and to alter response to treatment

We next interrogated whether the RASSF1A-mediated regulation of HES1 could occur through the NOTCH-HES1 axis. As HES1 has been directly implicated in SC marker upregulation in various cancer settings (Reedijk *et al*, 2008; Gao *et al*, 2014; Fender *et al*, 2015; Jin *et al*, 2017; Fendler *et al*, 2020), we used NANOG expression as a readout for SC marker expression. To address the potential involvement of RASSF1A in NOTCH signaling, we employed collagen 3D-

HeLa spheroid assays to mimic the *in vivo* tumor microenvironment. Supporting this model with the NOTCH ligand Delta-like Canonical Notch Ligand 4 (DLL4) resulted in an elevation of HES1 and cancer stemness (NANOG) (Fig 3A and B, DLL4 vs Control). Intriguingly, we find that reduction of RASSF1A levels not only increased baseline HES1 in the absence of ligand but also rendered HES1 and NANOG levels insensitive to the downstream effects of the GSI dibenzazepine (DBZ) which prevents NOTCH cleavage (Figs 3A and B, and EV4D). This suggests that Notch activation and RASSF1A loss independently stabilize HES1 levels and that RASSF1A controls HES1 and NANOG levels even when Notch receptor cleavage is perturbed (Fig 3B). To confirm this finding, we additionally implemented DAPT as an independent GSI in our system, and again found that RASSF1A loss rendered cells irresponsive to the downstream effects of the treatment, as indicated by the unaltered HES1 levels (Fig 3C).

In order to validate NOTCH-HES1-dependent regulation of pluripotency markers in response to RASSF1A, we depleted HES1 in U2OS and HeLa cells lacking RASSF1A and found that sufficient to rescue SC marker increase (Fig EV5C). Conversely, ectopic expression of HES1 led to upregulation of all core pluripotency markers (Fig EV5D). To address our findings in a genetically clean system constantly expressing core SC genes, we employed *Rassf1a*^{WT} or *Rassf1a*^{KO} induced pluripotent stem cells (iPSC) deriving from mouse embryonic fibroblasts (MEFs) as previously described (van der Weyden *et al*, 2012; Papatyropoulos *et al*, 2018) (Fig 3D). By utilizing mouse E14Tg2a ESCs and our *Rassf1a*-proficient iPSC lines (*Rassf1a*^{WT} iPSC), we confirmed that all core pluripotency markers decreased upon DBZ treatment and increased upon addition of DLL4, following *Hes1* regulation, as expected (Figs 3E and EV4E). However, genetic ablation of *Rassf1a* (*Rassf1a*^{KO} iPSC) rendered iPSCs insensitive to the downstream effects of DBZ treatment, while DLL4 had a redundant effect with regards to SC marker expression (Fig 3E), thereby corroborating our findings in tumor cells. Taken together, our data strongly imply that Notch-independent, HES1 stabilization in response to RASSF1A loss may actively contribute to increased SC marker expression.

HES1 has been implicated in chemotherapy resistance, deriving from its capacity to promote cancer stem cell self-renewal (Liu *et al*, 2015). HES1-mediated multidrug resistance has been widely attributed to STAT3 upregulation and p21 suppression (Liu *et al*, 2015). HES1 has been found to activate STAT3 (Kamakura *et al*, 2004; Zhou *et al*, 2013), which in turn induces *Nanog* and *Oct4* transcription in ESC and iPSC through direct binding at the distal enhancers of the

genes (Do *et al*, 2013). Interestingly, although a link between RASSF1A and STAT3 has not been identified yet, RASSF1A was found to upregulate p21 in cancer cells (Thaler *et al*, 2009), which may contribute to the removal of the drug resistance barrier in RASSF1A-expressing tumors. Thus, besides RASSF1A itself, clinical patient response may be further stratified based on p21 levels; however, this warrants further investigation. Along the same lines, the expression levels of pluripotency genes may help stratify patient response based on our data demonstrating that core stem cell marker levels are directly reciprocal to RASSF1A activity in cancer cells.

In the present study, for the first time, we provide evidence of a RASSF1A-mediated regulation of the NOTCH effector HES1, independent of the RASSF1A role as a Hippo pathway scaffold. Our results provide mechanistic insight into RASSF1A-HES1 regulation, by identifying the E3 ligase SNURF/RNF4 as a critical component of HES1 stability leading to its ubiquitination upon RASSF1A activation. Moreover, we demonstrate that GSIs are likely inefficient in tumors lacking RASSF1A, as HES1 levels remain stabilized regardless of upstream Notch signals. We additionally show that reciprocal RASSF1A-HES1 regulation is observed in the vast majority of human malignancies, indicating that our identified mechanism may play a critical role in the dedifferentiation process of all tumor types (Fig 4).

Different types of oncogenic stimuli can have a varying impact on tumor suppressor activation and subsequent phenotypes (Velimezi *et al*, 2013; Galanos *et al*, 2016; Gorgoulis *et al*, 2019; Lagopati *et al*, 2021; Zampetidis *et al*, 2021). RASSF1A is a pleiotropic tumor suppressor protein, which, in response to different signals, is involved in a plethora of biological functions such as cell cycle control, cellular metabolism, and differentiation (Dubois *et al*, 2019). Our results provide a mechanistic explanation for the role of RASSF1A in tumor dedifferentiation, verified clinically through the analysis of a wide range of human tumor types, consisting of large patient cohorts. In the last few years, GSIs have been in the spotlight of cancer research, exploring their potential clinical implementation in numerous clinical trials (Ran *et al*, 2017; Cook *et al*, 2018; Pine, 2018). In our study, we demonstrated that GSIs may be inefficient in tumors lacking RASSF1A; however, in tumors maintaining RASSF1A expression, GSI-based treatments would likely further contribute to HES1 inactivation. In line with our model, previous research has shown that in tumor types maintaining high levels of RASSF1A such as leukemias (Fig 1A), treatment of patient xenografts with GSIs *in vivo* decreases tumor burden and prolongs overall survival (Habets *et al*, 2019; Sohani *et al*, 2021). Conversely, clinical trials in small cohorts of lung cancer patients or wider cohorts of ovarian cancer

**Figure 4. Model.**

RASSF1A loss leads to HES1 stabilization in a Hippo pathway-independent mechanism involving the E3 ligase SNURF/RNF4. In the absence of RASSF1A, HES1 levels remain unaffected by GSIs such as DBZ and DAPT. RASSF1A activation induces SNURF/RNF4-mediated HES1 degradation via targeted HES1 ubiquitination. GSIs may further destabilize HES1 in the presence of RASSF1A. The RASSF1A status may constitute a robust biomarker of the effectiveness of Notch inhibitors in precision oncology.

patients where RASSF1A levels are traditionally low (Fig 1B), demonstrated insufficient activity of GSIs against cancer progression (Krop *et al*, 2012; Diaz-Padilla *et al*, 2015; Messersmith *et al*, 2015).

Taken together, our data identify RASSF1A as a clinical biomarker predicting individual patient response to therapy with potential inhibitors of the NOTCH-HES1 axis, thereby delineating the clinical setting where treatment with such inhibitors might be a productive therapeutic avenue against cancer progression at the patient level.

Materials and Methods

Cell lines and reagents

U2OS, HeLa, and H1299 cells were grown in Dulbecco's modified Eagle's medium (DMEM) containing 10% fetal calf serum

(Gibco). U2OS Tet-On cells (Clontech) inducibly expressing FLAG-RASSF1A upon doxycycline administration were established as described in the manufacturer's protocol (Yee & O'Neill, 2010). E14Tg2a mouse embryonic stem cells and iPS cells were maintained in culture as previously described (Papaspyropoulos *et al*, 2018). All cell lines were provided from the American Type Culture Collection (ATCC) and Clontech and were maintained in culture for no longer than 2 months. Cell counting was carried out using C-Chip disposable counting chambers (NE63508-01) (Wiener *et al*, 2018).

For Notch stimulation or inhibition, Delta like ligand 4 (DLL4; R&D Systems) and γ -secretase inhibitors DBZ (R&D Systems) and DAPT were, respectively, used. DLL4 was either added directly in cell medium at 1 $\mu\text{g}/\text{ml}$ or used at the same concentration in coating gelatinized plates in 0.1% gelatin for 2 h. Plates were washed with PBS before cells were seeded. DBZ was added in the media at

100 nM and DAPT at 50 μ M. Cells were harvested 24 h after treatment.

Co-immunoprecipitation

For lysate preparation, cells were lysed in ice-cold 1% (v/v) Nonidet P40 lysis buffer (20 mM Hepes pH 7.5, 1% NP40 (Roche), 150 mM NaCl, 0.5 mM EDTA, 50 mM NaF, 10 mM β -glycerophosphate, 0.5 mM Na_3VO_4 , and 1 \times EDTA-free protease inhibitors (Roche)). Lysates were centrifuged at 4°C at 10,000 *g* for 10 min and were subsequently subjected to sonication for 15 s at 20% amplitude. Samples were normalized with Bradford protein assay and equal protein volumes (1–2 mg) were used per reaction in each experiment. Immunocomplexes were precipitated with Protein G sepharose (Sigma) or Protein G Dynabeads (Life Technologies). The antibodies used were as follows: anti-YAP (H-125; sc-15404), anti-YAP (clone 63.7; sc-101199), anti-TAZ (H-70; sc-48805), anti-TAZ (Ab118373), and anti-HES1 (AB5702). IPs were incubated on an end-to-end rotator for 3 h at 4°C. The beads were then washed three times with NP40 wash buffer. IP samples were resuspended in 50 μ l 1 \times Laemmli sample buffer (12.5% glycerol (v/v), 2% SDS (w/v), 78 mM Tris pH 6.8, 720 mM β -mercaptoethanol, bromophenol blue) and boiled (100°C; 5 min).

Immunoblotting

Immunoblotting from immunoprecipitates and cell lysates was carried out as previously described (Pefani *et al*, 2014; Tzekaki *et al*, 2021a,b). The following primary antibodies were used at a concentration of 1:1,000; β -CATENIN (sc-7199), p73 (ep436Y), YAP (sc-15404 and sc-101199), HES1 (AB5702), GAPDH (Abcam; 2251-1; 1/10,000), TAZ (sc-48805 and Ab118373), FLAG (M2; Agilent; 200472-21), RASSF1A (sc-58470), NANOG (Cell Signaling; 4893S), OCT4 (ab19857), SOX2 (MAB4423; 1/500), LAMIN B1 (Ab16048; 1/10,000), RNF4 (Novus Biologicals), TEAD1 (BD Transduction Laboratories; 610922), p73 (EP436Y; 1/2,000), Ub (Cell Signaling; 3936), HA (Cell Signaling; 3724S), ICN1 (Cell Signaling; 4147S), β -ACTIN (Cell Signaling; 4967L), and HRP-conjugated anti-mouse and anti-rabbit secondary antibodies were used at a concentration of 1:5,000 (Jackson ImmunoResearch).

Nuclear/cytoplasmic fractionation

Cell fractionation was performed using the NE-PER Nuclear and Cytoplasmic Extraction Reagents Kit (Thermo Scientific). Briefly, 5×10^6 cells were harvested with trypsin-EDTA and centrifuged at 500 *g* for 5 min in a 1.5-ml microcentrifuge tube. The cells were then rinsed with PBS and centrifuged at 500 *g* for 3 min. The supernatant was carefully removed and the cell pellet was resuspended in ~ 100 μ l ice-cold CER I reagent (depending on the size of the cell pellet), vortexed, and incubated on ice for 10 min. Following that, 5 μ l ice-cold CER II reagent was added to the tube, which was vortexed and incubated on ice for 1 min. After vortexing again, the tube was centrifuged for 5 min at maximum speed and the supernatant (cytoplasmic extract) was immediately transferred to a pre-chilled tube, which could be stored at -20°C . The insoluble fraction (pellet) was then suspended in ~ 50 μ l ice-cold NER reagent and was vortexed for 15 s every 10 min for 40 min in total. Lastly, the tube was

centrifuged at maximum speed for 10 min and the supernatant (nuclear extract) could be stored at -80°C in a microcentrifuge tube.

Mass spectrometry

Samples were prepared according to the co-immunoprecipitation protocol from whole cell lysates with a few modifications. Only Protein G Dynabeads (Life Technologies) were used. After incubation on an end-to-end rotator for 3 h, the immunoprecipitates were washed four times, the two first being with NP40 lysis buffer and the last two only with filtered PBS. Tubes were subsequently left uncapped to air-dry for approximately 15 min. Mass spectrometry analysis was performed using an Orbitrap mass spectrometer. The CRAPome database (Mellacheruvu *et al*, 2013) was used to discard false-positive targets frequently found to precipitate with FLAG.

In vivo ubiquitination assay

U2OS cells were transfected with non-targeting siRNA (siCTRL)/pCDNA3, siCTRL/FLAG-RASSF1A, and siRNF4/FLAG-RASSF1A using Lipofectamine 2000 (Invitrogen). 48 h following transfection, cells were treated with MG-132 proteasome inhibitor (C2211, Sigma-Aldrich) for 3 h at 30 μ M and subsequently lysed in RIPA buffer (Tris-HCl at pH 8.0, 50 mM, NaCl 150 mM, SDS 0.1%, sodium deoxycholate 1%, Triton X-100 1% and protease (#58440, Pierce, Thermo Scientific), phosphatase (#78420, Pierce, Thermo Scientific) inhibitor cocktail and N-Ethylmaleimide deubiquitinase inhibitor (04259, Sigma-Aldrich)). U2OS^{Tet ON - FLAG-RASSF1A} cells with and without treatment with 0.5 μ g/ml of Doxycycline, as well as U2OS cells transfected with siCTRL and siRASSF1A were subjected to nuclear/cytoplasmic fractionation prior to *in vivo* ubiquitination assay. Protein lysates were precleared with protein G agarose beads (#16-266, Millipore) for 1 h and then incubated with G-protein beads bound to HES1 antibody (AB5702) for 2 h at 4°C. Cell lysates and immunoprecipitates were analyzed in Western blotting.

In vitro ubiquitination assay

The assay was carried out in 1 \times E3 ligase Reaction Buffer (R&D Systems; B-71) with the addition of the following reaction components up to a final volume of 25–50 μ l: 100 nM Recombinant Human His6-Ubiquitin E1 Enzyme (UBE1, R&D Systems; E-304), 1 μ M E2 Enzyme UBCH5a/UBE2D1 (R&D Systems; E2-616), 100 μ M Recombinant Human Ubiquitin (R&D Systems; U-100H), and 10 mM Mg^{2+} -ATP solution (R&D Systems; B-20). 5 μ M of purified HES1 (Origene; TP311709), 1 μ M of purified RNF4 (Origene; AR50585PU-S), and/or 5 μ M of purified RASSF1 (Origene; AR50639PU-S) were added to the reaction mix. All reactions were incubated at 37°C for 1 h. As a negative control, no Mg^{2+} -ATP was added to the reaction mix. Reactions were terminated with the addition of 2 \times SDS-PAGE sample buffer. After boiling at 100°C for 5 min, the reactions were subjected to Western blotting.

qPCR analysis

Quantitative Real-Time PCR was carried out according to the Power SYBR Green Cells-to-Ct kit protocol (Applied Biosystems), as previously described (Papaspyropoulos *et al*, 2018). For qRT-PCR following ChIP and ChIP seq, the Input samples were at a concentration of

2.5 ng/μl. The following primers were used for human genes: *HES1* FW: ATTCCTCGTCCCCGGTGGCT and REV: GCTTGGAAATGCC GCGAGTATCTTT, *NANOG* FW: GGTGTGACGCAGAAGGCCTCA and REV: CCCAGTCGGGTTACCAGGCA, *OCT4* FW: CCTGAAGCAG AAGAGGATCACC and REV: AAAGCGGCAGATGGTCGTTTGG, *SOX2* FW: GAGCTTTGCAGGAAGTTTGC and REV: GCAAGAAGCCTC TCCTTCAA, *RNF4* FW: AAGTGGTTGCTGTTGAGGC and REV: CCAGTATTTCAAGTCCGCTGC, *GATA1* FW: CACGACACTGTGG CGGAGAAAT and REV: TTCCAGATGCCTTGC GGTTTCG, 18S FW: AGTCCCTGCCCTTTGTACACA and REV: GATCCGAGGGCCTCACT AAAC and *OCT4* promoter (Cell Signaling; 4641). The following primers were used for mouse genes: *Hes1* FW: CAACACGACACCGG ACAAAC and REV: GGAATGCCGGGAGCTATCTT, *Nanog* FW: AG GGTCTGCTACTGAGATGCTCTG and REV: CAACACTGGTTTTT CTGCCACCG, *Oct4* FW: CTGAGGGCCAGGCAGGAGCAGGAG and REV: CTGTAGGGAGGGCTCGGGCACTT, *Sox2* FW: CAGGAGTTG TCAAGGCAGAGA and REV: CTTAAGCCTCGGGCTCCAAA, *Gapdh* FW: CTCCACTCACGGCAAATTCA and REV: CGCTCCTGGAAGA TGTTGAT.

Immunofluorescence

Cells were seeded and cultured either on coverslips or collagen-coated wells with defined stiffness of collagen matrix as previously described (Pankova *et al*, 2019). Cell mounting was done onto microscope slides using Prolong Gold antifade reagent with DAPI (Life Technologies). Images of the cells were acquired using a Nikon 90i microscope with the NIS elements software, a Leica DM IRBE microscope with Simple PCI6 software or a Zeiss LSM710 confocal microscope with the Zeiss ZEN software. The following primary (dilution 1:100) and secondary (dilution 1:500) antibodies were used: NANOG (Cell Signaling; 4893S), SOX2 (MAB4423), HES1 (AB5702), Alexa fluor goat anti-rabbit and anti-mouse (Invitrogen).

Immunofluorescence staining in 3D collagen

HeLa multicellular tumor spheroids were generated according to the hanging-drop method as previously described (Foty, 2011; Pankova *et al*, 2019). In brief, HeLa cells were detached with 2 mM EDTA and re-suspended in medium containing methylcellulose (20%, Sigma-Aldrich) and Matrigel (1%, Corning, Growth factor reduced). Cells were incubated as hanging droplets (25 μl) containing 2,000 cells for 48 h to generate multicellular aggregates. For 3D spheroid staining, collagen-spheroid gels were washed with PBS, fixed with 4% PFA, and cross linked in sodium azide solution overnight. Spheroids were incubated in primary antibodies (see Immunofluorescence section, all diluted 1: 100), diluted in Triton and 10% NGS overnight, washed, and incubated in secondary antibodies (see Immunofluorescence section, dilution 1:1,000) overnight at 4°C. Spheroids-collagen gels were washed with PBS, mounted with DAPI, and following gel polymerization, cells were stained using the Immunofluorescence protocol above. Images were obtained by using Nikon 20×/0.30 Ph1 objectives.

Three-dimensional Matrigel differentiation assay

H1299 multicellular tumor spheroids were generated using the hanging-drop method. Aggregates were washed and cultured on Matrigel (8 mg/ml, Corning, Reduced growth factors) for 24 h.

Images were obtained every 30 min at 37°C using a motorized inverted Nikon Ti microscope (4×/0.10 NA air objective lens) connected to a Nikon camera.

DNA constructs and siRNA experiments

For siRNA-mediated silencing and transient plasmid expression in all cell lines, Lipofectamine 2000 (Invitrogen) was used according to manufacturer instructions. The following oligonucleotides were used for siRNA-mediated silencing: non-targeting (CTRL): UAAG-GUAUGAAGAGAUAC (Dharmacon), RASSF1A: GACCUCUGUGCGG ACUUCA, YAP1: CUGGUCAGAGAUACUUCUUt (Eurofins MWG). siRNAs to TAZ (GS25937), RNF4 (GS6047), HES1 (GS3280), and GATA1 (GS2623) were purchased from Qiagen. The following plasmids were purchased from Addgene: p2xFLAGhYAP1 (#17791) and p2xFLAGhYAP1-S127A (#17790). The GFP-HES1 plasmid vector was purchased from Origene (#RG211709).

Chromatin immunoprecipitation

ChIP was performed according to the ChIP-IT High Sensitivity kit (Active Motif) as previously described (Papaspyropoulos *et al*, 2018). Binding to promoter regions was assessed via qPCR. YAP (clone 63.7;sc-101199) and TAZ (sc-48805) antibodies were used for the immunoprecipitations. An IgG antibody (Cell Signalling; 2729 S) served as control.

Bioinformatics analyses

Raw RNA-seq read count data for 34 publicly available tumors and available adjacent normal tissues were downloaded from The Cancer Genome Atlas (TCGA) database (<https://www.cancer.gov/tcga>) (Cancer Genome Atlas Research Network *et al*, 2013). For correlation heatmaps, the average RSEM (log₂) value per gene of interest was calculated from all replicates per tumor. Spearman's correlation was performed after calculating Euclidean distance on the ranked values of the dataset. Hierarchical clustering was applied in columns and rows. Heatmaps were constructed in R using the ggplot2 package (<https://ggplot2.tidyverse.org/>) (Wickham, 2016). In order to categorize the expression of genes as high and low, the average RSEM(log₂) from all the available replicates per cancer was calculated, and afterward, the median value was selected as a threshold (> median → high, < median → low). All values can be found in Appendix Table S1.

Statistical analysis

For all experiments reported in this manuscript, at least three biological replicates were used and statistical significance was determined by Student's *t*-test.

Data availability

No primary datasets have been generated and deposited. The authors declare that all data supporting the findings of this study are available within the article and its supplementary information files or from the corresponding authors upon reasonable request.

Acknowledgements

This work was supported by CRUK A19277, MRC, Kidani Memorial Trust, the Federal Agency for Scientific Organizations (FASO Russia grant No. 0324-2016-0008), the Wellcome Trust and the Science Foundation Ireland (grant No. 15/CDA/3495). This research was also co-financed by Greece and the European Union (European Social Fund- ESF) through the Operational Program «Human Resources Development, Education and Lifelong Learning» in the context of the project “Reinforcement of Postdoctoral Researchers - 2nd Cycle” (MIS-5033021), implemented by the State Scholarships Foundation (IKY); the Hellenic Foundation for Research and Innovation (HFRI) and the General Secretariat for Research and Innovation (GSRI), under the grant agreement No 775, entitled “Hippo pathway in genome and epigenome maintenance – HIPPO”; the HFRI and the GSRI, under the grant agreement No 3782, entitled “Interrogating the Pathophysiological Consequences of deregulated Replication Licensing – PaCoRel”; the European Union’s Horizon 2020 research and innovation program under the Marie Skłodowska-Curie grants agreement no. 722729 (SYNTRAIN); the National Public Investment Program of the Ministry of Development and Investment / General Secretariat for Research and Technology, in the framework of the Flagship Initiative to address SARS-CoV-2 (2020ΣΕ01300001); the Welfare Foundation for Social & Cultural Sciences (KIKPE), Athens, Greece; the H. Pappas donation; the NKUA-SARG grants 70/3/8916 and 70/3/12128.

Author contributions

AP, EON, and VG designed the study, analyzed, and interpreted data. AP, AA, IM, DP, and KT performed experiments. AikP performed bioinformatics analyses. SL, NL, AK, and KE assisted with experiments and manuscript preparation. AAP and EC contributed toward data interpretation. AP, EON, and VG wrote the manuscript and supervised the project.

Conflict of interest

The authors declare that they have no conflict of interest.
